## Measure Theory and Filtering

### Introduction and Applications

The estimation of noisily observed states from a sequence of data has traditionally incorporated ideas from Hilbert spaces and calculus-based probability theory. As conditional expectation is the key concept, the correct setting for filtering theory is that of a probability space. Graduate engineers, mathematicians, and those working in quantitative finance wishing to use filtering techniques will find in the first half of this book an accessible introduction to measure theory, stochastic calculus, and stochastic processes, with particular emphasis on martingales and Brownian motion. Exercises are included, solutions to which are available from [www.cambridge.org](http://www.cambridge.org). The book then provides an excellent user's guide to filtering: basic theory is followed by a thorough treatment of Kalman filtering, including recent results that extend the Kalman filter to provide parameter estimates. These ideas are then applied to problems arising in finance, genetics, and population modelling in three separate chapters, making this a comprehensive resource for both practitioners and researchers.

LAKHDAR AGGOUN is Associate Professor in the Department of Mathematics and Statistics at Sultan Qabos University, Oman.

ROBERT ELLIOTT is RBC Financial Group Professor of Finance at the University of Calgary, Canada.

CAMBRIDGE SERIES IN STATISTICAL AND  
PROBABILISTIC MATHEMATICS

---

*Editorial Board*

- R. Gill (Department of Mathematics, Utrecht University)  
 B. D. Ripley (Department of Statistics, University of Oxford)  
 S. Ross (Department of Industrial Engineering, University of California, Berkeley)  
 M. Stein (Department of Statistics, University of Chicago)  
 B. Silverman (St. Peter's College, University of Oxford)

This series of high-quality upper-division textbooks and expository monographs covers all aspects of stochastic applicable mathematics. The topics range from pure and applied statistics to probability theory, operations research, optimization, and mathematical programming. The books contain clear presentations of new developments in the field and also of the state of the art in classical methods. While emphasizing rigorous treatment of theoretical methods, the books also contain applications and discussions of new techniques made possible by advances in computational practice.

# Preface

Traditional courses for engineers in filtering and signal processing have been based on elementary linear algebra, Hilbert space theory and calculus. However, the key objective underlying such procedures is the (recursive) estimation of indirectly observed states given observed data. This means that one is discussing conditional expected values, given the observations. The correct setting for conditional expected value is in the context of measurable spaces equipped with a probability measure, and the initial object of this book is to provide an overview of required measure theory. Secondly, conditional expectation, as an inverse operation, is best formulated as a form of Bayes' Theorem. A mathematically pleasing presentation of Bayes' theorem is to consider processes as being initially defined under a "reference probability." This is an idealized probability under which all the observations are independent and identically distributed. The reference probability is a much nicer measure under which to work. A suitably defined change of measure then transforms the distribution of the observations to their real world form. This setting for the derivation of the estimation and filtering results enables more general results to be obtained in a transparent way.

The book commences with a leisurely and intuitive introduction to  $\sigma$ -fields and the results in measure theory that will be required.

The first chapter also discusses random variables, integration and conditional expectation.

Chapter 2 introduces stochastic processes, with particular emphasis on martingales and Brownian motion.

Stochastic calculus is developed in Chapter 3 and techniques related to changing probability measures are described in Chapter 4.

The change of measure method is the basic technique used in this book.

The second part of the book commences with a treatment of Kalman filtering in Chapter 5. Recent results, which extend the Kalman filter and enable parameter estimates to be obtained, are included. These results are applied to financial models in Chapter 6. The final two chapters give some filtering applications to genetics and population models.

The authors would like to express their gratitude to Professor Nadjib Bouzar of the Department of Mathematics and Computer Science, University of Indianapolis, for the incredible amount of time he spent reading through the whole manuscript and making many useful suggestions.

Robert Elliott would like to acknowledge the support of NSERC and the hospitality of the Department of Applied Mathematics at the University of Adelaide, South Australia.
